Abstract Three new species of *Macrophya* Dahlbom from China are described; *M. incrassitarsalia* Wei et Wu, sp. nov., *M. melanosomata* Wei et Xin, sp. nov. and *M. leucotrochanterata* Wei et Li, sp. nov. All the three new species are members of *M. erythrochanterata* group. The type specimens of the new species are deposited in the Insect Collection of Central South University of Forestry and Technology, Changsha, Hunan, China.

Macrophya incrassitarsalia Wei et Wu, sp. nov. (Figs 1-14)

Body length 10.0 mm in female and 7.5 mm in male. The new species is a member of M. erythrochema group. M. incrassitarsalia differs from all other species of the species group in the dorsal side of head and thorax densely and roughly punctured, without shining interspaces; mesoscutellum and trochanters black entirely; the hind basitarsus strongly enlarged and compressed; the middle part of mesepisternum distinctly elevated, with an oblique carina; the cell 2Rs longer than cell 1Rs distinctly; middle serrulae flat with 1 proximal subbasal teeth and 10-11 distal subbasal teeth. The strongly enlarged metabasitarsus is unique in M. erythrochema group. All other species of the group have long and slender metabasitarsus.

Body length 8.5 mm in female and 7.0 mm in male. The new species is a member of M. erythrocnema group and is similar to M. pentanalia Wei & Chen, 2002. M. melanosomata differs from M. pentanalia in the emargination of clypeus shallow and about 1/5 length of clypeus, the lateral lobes of clypeus short and obtuse; the frons not depressed, above the top of eyes; postocellar area, pronotum, mesoscutellum and abdominal tergites black entirely; the hind trochanter almost entirely black; the female serrulae weakly protruding, the middle serrulae each with 1 proximal subbasal tooth and 10-11 distal subbasal teeth. In M. pentanalia, the emargination of clypeus quite deep and about 1/2 length of clypeus, the lateral lobes very long and acute; the frons depressed, below the top of eyes; the posterior margin of postocellar area, the posterior of pronotum and middle of mesoscutellum white; the ventral side of the 2nd - 3rd abdominal tergites and the middle part of the 8th - 10th abdominal tergites with white macula; hind trochanter largely white; the female serrulae distinctly protruding, the middle serrulae each with 1 proximal subbasal tooth and 4 - 5 distal subbasal teeth.
